

Executive summary — Claude session 01, Russell Capital Systems

Date: 2026-09-18 · **Repo:** samtheinsuranceman-debug/sam-russell-corpus, folder russell-capital-systems/, branch master · **Owner:** Samuel A. Russell V

The finding that should be read first

There are two codebases, and one of them runs nowhere.

russell-capital-systems/ is the deployed app: 502 TypeScript files, 125 shared engines, 201 test files, a package.json, a router, and Railway deploying from it.

russell-capital/ holds 80 TypeScript files and 20 shared engines with 11 test files — and has **no** package.json, **no** server/routers.ts, **and nothing in the deployed app imports it**. Roughly **5,900 lines of finished, tested engine code executes nowhere**. Inside the deployed folder there is a smaller instance of the same problem: timeMachine30.ts (666 lines, 287-line test) appears in no route, no catalogue entry and no memory group.

This is not dead code. It is good code in the wrong folder — an adverse-scenario stress tester, a full property-and-loan amortisation engine, an illustration-compliance layer, a small-business lending vertical, a lender-ranking module. Recovering it is the highest-value task on the board, ahead of anything in the previous roadmap, because the work is already paid for. master_build_correlation.md has the file-by-file table; data/master_build_inventory.csv has it machine-readable with priorities.

And the best idea in the repository is not mine. The other session's UnsourcedFindingError and UnsourcedQuoteError make "no figure without a source" a runtime error that *throws*. My approach — Verified<T> plus guard tests that scan source text — catches a class of error at build time but cannot catch a value born at runtime. Theirs is strictly stronger and should become the house standard.

What was asked, across the session

Turn the Wealth Genome from one insurability shape into two dozen strategies; add a spouse-pairing protocol with consent and per-asset veto weights; build the cycle engine behind "infinite banking" and say honestly whether any cycle is infinite; generate every useful combination and ordering of the five capital mechanisms with confidence and likelihood scores; research and encode the thresholds lenders actually apply and every legitimate way they move; produce thousands of legal, situation-specific, stage-by-stage plans for portfolio owners; wire all of it into the twelve-channel AI brain and a memory bank; rate every major page for value and frequency and measure how wired each one is; hand the unresolved work to Perplexity with a roadmap and criteria; and correlate everything against the most recent master saves.

What was built

Layer	Result
Genome	24 strategies with signals, gates and allocation; silence ≠ evidence — an unanswered factor lowers confidence rather than raising a score. Household pairing: 21 factor rules, influence = title×0.5 + exposure×0.25 + dependence×0.25, veto pull = 2×min(w, 1−w).
Cycle engine	Five mechanisms with real constraints; twenty-year simulation whose headline is the break year . Proved the equity-share "infinite cycle" turns exactly once on one property. BRRRR break-even uplift ≈ 1.34.
Orderings	Position is a role (source / converter / sink). Two covenant rules prune 120 permutations to 40. 42 orderings carrying share, confidence and likelihood as three separate numbers.

Layer	Result
Thresholds	14 gates with source URLs: delayed financing = 0-month seasoning capped at documented cost; portfolio DSCR escapes the ten-property cap at 4–5 properties; no Garn-St Germain exemption covers a wrap . Fixed gates name the statute.
Planner	Covenants tracked per property . 13 moves. 9,423 legal plans at depth 4 for a thirty-house owner, 79,035 at depth 5 — counted by a test. Beam search to 24 stages in well under a second. On a payoff goal it says the unwelcome true thing: sell eleven of thirty to clear 72% of debt in 3.8 years.
Archetypes	Twelve named shapes, up to 22 stages, run through the planner at render time so prose cannot drift from arithmetic.
Dossiers	Per mechanism: mechanics with the governing clause, 39 providers, conditions, interop, and value and frequency rated separately (policy loan 7/2; velocity 5/6).
Façades (this turn)	<code>realEstateCapitalStackEngine.ts</code> and <code>historicalMarketRegimeEngine.ts</code> — one Situation in, the whole stack out; one year in, the regime and its conditional base rates out. 17 tests.
Brain + memory	29 groups wired to the twelve channels; priority-1 never trimmed.
Scorecard	Every page scored on ten wiring dimensions read from the code . Mean 3.3 / 10 ; none at ten; 76 of 115 below five. 52 pages rated for value and frequency with the connections to reach ten.
Tests	193 files, 3,439 tests green. 321 routes.

What stopped short, and why

- 39 provider names come from general knowledge; by the site's own publishing rule they carry no rates, terms or contacts until read from primary sources. `provider_verification_brief.md` is the instruction set.
- Equity-share investment-property eligibility and subordinate-lien consent could not be verified at **any** of the five providers — the fact that most changes the planner's legal space.
- Owner-only: Railway variables, MCP authorisations (OpenRouter, Speko, Stripe), a provisional patent filing, production feed verification from outside.
- No account aggregation; every projection runs from typed inputs.

The numbers worth remembering

3.3 / 10 — mean page wiring. The engines are strong; the connections are the work.

~5,900 — lines of finished engine code currently executing nowhere.

9,423 — legal plans for a thirty-house owner at four stages, up from the 40 orderings a single-property model allowed.

14 and 5 — historical windows behind the "left" and "right" ten-year tax buckets. Both thin, so the engine returns `null` for the power swing rather than a number. That refusal is the house style.

0 of 57 — patent claims filed. One provisional record makes every "patent pending" surface true.

Where to start

1. `master_build_correlation.md` — the two-codebase finding and the integration order.
2. `recommendations.md` §3 **P0a** (recover the orphaned code), then **P0b** (the provider research).
3. `provider_verification_brief.md` — Perplexity's first research job.
4. `value_multipliers_25.md` and `experience_upgrades_25.md` — what to build once the foundation is sound.
5. `data/questions.csv` — every open question with the exact file its answer belongs in.
